We consider a new Lie-algebraic framework for the Pöschl-Teller potential, in which a single \([\text{sp}(2,\mathbb{R}) \text{Casimir}]\) operator has both bound and scattering states. This approach allows the determination of the \(S\) matrix by purely algebraic means.

Symmetry methods have been successfully applied in a wide variety of systems in physics. Symmetry and dynamical algebras (and their groups) have proved useful tools in the analysis of bound-state problems, ranging from exact solutions, as in the Coulomb\(^1\) and harmonic oscillator\(^2\) potentials, to algebraic models of physical systems, such as the interacting-boson-model description of collective states in nuclei.\(^3\) In contrast, little has been done in the application of algebraic methods to scattering, with the exception of the Coulomb system, where the bound and scattering states have been analyzed separately in terms of the groups \(SO(4)\) and \(SO(3,1)\), respectively. In that case, one may also imbed the two into a \(SO(4,2)\) dynamical group.\(^4\)

In a recent series of papers,\(^5-7\) Alhassid, Gürsey, and Iachello have shown that bound and scattering states of certain one-dimensional potentials can be related to unitary representations of a certain group and its analytic continuation to a noncompact group, respectively.\(^5-7\) These ideas are illustrated on the Morse and Pöschl-Teller potentials, where the reflection and transmission coefficients (or the \(S\) matrix) are evaluated by obtaining the explicit wave functions and studying their asymptotic behavior. In these cases the relevant group chains are \(U(2) \supset O(2)\) for bound states and \(U(1,1) \supset O(1,1)\) for scattering states. This procedure seems to provide a fruitful pathway for the study of continuous spectra as the analytic continuation of bounded spectra.

We deem it desirable, however, to study a different formulation for systems with mixed spectra. The objective of this Letter is to present one such alternative applied to the Pöschl-Teller potential,\(^8\) which emerges in connection with diverse physical systems, such as completely integrable many-body systems in one dimension,\(^9\) the soliton solutions to the Korteweg–de Vries equation,\(^10\) and in the Hartree mean-field equation of many-body systems interacting through a \(\delta\) force\(^11\) among others. This approach has two attractive features: (i) Both the bound and the scattering states belong to representations of the same group and (ii) the \(S\) matrix can be determined by purely Lie-algebraic manipulations, with no need for the explicit form of the wave functions.

We start our discussion by considering an \(\text{sp}(2,\mathbb{R}) \equiv \text{so}(2,1)\)\(^4\) algebra generated by operators \(J_x, J_y,\) and \(J_z,\) satisfying the well-known commutation relations\(^4\)

\[
[J_x, J_y] = -iJ_z, \quad [J_x, J_z] = iJ_y, \quad [J_y, J_z] = iJ_x, \quad (1)
\]

with Casimir invariant \(J^2 = J_x^2 - J_y^2 - J_z^2.\) This algebra has the realization

\[
J_x = -i(x \partial_y + y \partial_x), \quad J_y = i(x \partial_z + z \partial_x), \quad J_z = -i(x \partial_y - y \partial_x). \quad (2)
\]

With the introduction of polar hyperbolic coordinates \(x = r \cosh \rho \cos \theta, \quad y = r \cosh \sin \theta, \quad z = r \sinh \rho,\) and the similarity transformation by \(\Omega = \cosh \rho\) the weight function in the hyperboloid measure on \((r = \text{const}, \rho, \theta),\) the Casimir invariant and \(J_z\) take form

\[
J^2 = -\partial^2_{\rho} - \sech^2 \rho (\partial^2_{\theta} - \frac{1}{4}) + \frac{1}{4},
\]

\[
J_z = -i \partial_{\theta}. \quad (3)
\]

At this point we use the twofold cover of the hyperboloid, allowing \(\theta\) to range over \([0, 4\pi)\) and thus \(J_z\) to have half-integer as well as integer eigenvalues.

We now build the simultaneous, normalized eigenfunctions \(|km\rangle\) of \(J^2\) and \(J_z,\)\(^4\) classified by...
their eigenvalues:
\[ J^2 |km\rangle = k(1-k) |km\rangle, \quad J_z |km\rangle = m |km\rangle. \] (4)

The unitary nonexceptional representations\(^{12}\) of \(\text{sp}(2,R)\) may be divided into a continuous series \(C\) and a discrete series \(D\). The Bargmann index\(^{12}\) \(k\) and the \(\text{so}(2)\) content \(m\) follow:

\[ C: \quad k = \frac{1}{2} + i\kappa, \]
\[ \text{in } C_{1/4-k^2}^\kappa: \quad \kappa \geq 0, \quad m = 0, \pm 1, \pm 2, \ldots. \]
\[ \text{in } C_{1/4-k^2}^{1/2}: \quad \kappa > 0, \quad m = \pm \frac{1}{2}, \pm \frac{3}{2}, \ldots. \] (5a)

\[ D: \quad k = \frac{1}{2}, 1, \frac{3}{2}, 2, \ldots, \]
\[ \text{in } D_k^+: \quad m = k, k+1, k+2, \ldots. \]
\[ \text{in } D_k^-: \quad m = -k, -k-1, -k-2, \ldots. \] (5b)

The Casimir operator has thus a mixed spectrum which, as we show below, corresponds to the full spectrum of the Pöschl-Teller (PT) potential. The wave functions in (4) have the form
\[ I_{km} = u^m_k(\rho) e^{im\theta}, \] (6)
where \(u^m_k(\rho)\) satisfies the equation
\[ [-\partial_\rho^2 - \text{sech}^2 \rho (m^2 - \frac{1}{4})] u^m_k(\rho) = -(k - \frac{1}{2})^2 u^m_k(\rho), \] (7)
which is a PT Schrödinger equation where the depth of the well is given by the \(\text{so}(2)\) eigenvalue \(m\). The group \(\text{SO}(2,1)\) [twice covered by \(\text{Sp}(2,R)\)] generated by the above algebra was called "the potential group" in Ref. 6, but its properties were not examined further.

We see that (5b) together with (7) correctly describe the bound energy spectrum of the PT potential,\(^{6}\) since for a fixed \(m\) (i.e., for fixed potential) they imply
\[ E_k = -(k - \frac{1}{2})^2, \quad k = \frac{1}{2}, 1, \frac{3}{2}, \ldots, |m|. \] (8)

Our main interest in this Letter, however, is to consider Eq. (7) for the \(C\) representation series. Since now \(k = \frac{1}{2} + i\kappa\), with \(m\) being either integer (in \(C^0\)) or half-integer (in \(C^{1/2}\)), Eq. (7) now reads
\[ [-\partial_\rho - \text{sech}^2 \rho (m^2 - \frac{1}{4})] u^m_k(\rho) = \kappa^2 u^m_k(\rho). \] (9)
This is the scattering PT equation. To obtain the transmission and reflection coefficients or, equivalently, the \(S\) matrix, we proceed as follows. Using (2) in the covered hyperbolic coordinates, we define the raising and lowering operators
\[ J_\pm = (J_\mp \mp J_\gamma) = ie^{\pm i\theta}[\mp \partial_\rho + \text{tanh} \rho \mp i \partial_\theta]; \]
\[ J_\pm |km\rangle = [(\frac{1}{2} \pm m - i\kappa)(\mp \frac{1}{2} \mp m - i\kappa)]^{1/2} |k m \pm 1\rangle. \] (10)
(An operator \(J_\mp^{\pm}(\infty)\) may be defined similarly.) We write the \(\text{sp}(2,R)\) asymptotic basis functions as
\[ |\psi^-(\rho)\rangle = \lim_{\rho \to -\infty} |km\rangle = a_m e^{im\theta} e^{i\kappa \rho} + c_m e^{im\theta} e^{-i\kappa \rho}, \] (13a)
\[ |\psi^+(\rho)\rangle = \lim_{\rho \to +\infty} |km\rangle = b_m e^{im\theta} e^{i\kappa \rho}. \] (13b)
These are related to the PT asymptotic wave functions through
\[ u^\pm = \lim_{\rho \to \pm\infty} u^m_k(\rho) = e^{-im\theta} |\psi^\pm\rangle. \] (14)
Now, the limits of (12) and (13) yield
\[
\lim_{\rho \to \pm \infty} (J_{\pm} | km \rangle) = J_{\pm}^{(\pm \infty)} | \psi_{\pm} \rangle,
\]
which lead us directly to the following recurrence relations obtained from (11):
\[
a_{m+1} = \frac{\left( -\frac{1}{2} - m - i \kappa \right)}{\frac{1}{2} + m + i \kappa} a_m,
\]
\[
b_{m+1} = \frac{\left( \frac{1}{2} + m + i \kappa \right)}{\left( -\frac{1}{2} - m - i \kappa \right)} b_m,
\]
\[
c_{m+1} = -i \frac{\left( \frac{1}{2} + m - i \kappa \right)}{\left( -\frac{1}{2} - m + i \kappa \right)} c_m.
\]

Finally, since the PT potential with \( m = \frac{1}{2} \) in (7) corresponds to the free wave system, we see that \( a_{1/2} = b_{1/2} = c_{1/2} = 0 \). Equations (16) can be solved to give the transmission and reflection coefficients,
\[
T_m = \frac{b_m}{a_m} = \frac{\Gamma(\frac{1}{2} + m - i \kappa) \Gamma(\frac{1}{2} - m - i \kappa)}{\Gamma(1 - i \kappa) \Gamma(-i \kappa)},
\]
\[
R_m = \frac{c_m}{a_m} = 0,
\]
for \( m \) half-integer. These expressions have been obtained with use of only the Lie-algebraic properties of \( \text{sp}(2,R) \). Once \( T_m \) is known for all half-integer values of \( m \) we can analytically continue (17a) to real \( m \). This can be readily justified.\(^{13}\) It then follows from the unitarity and symmetry of the \( S \) matrix,\(^{14}\) which in this case is
\[
S_m = \begin{pmatrix} R_m & T_m \\ T_m & R_m \end{pmatrix},
\]
that
\[
R_m = \frac{\Gamma(i \kappa) \Gamma(\frac{1}{2} - m - i \kappa) \Gamma(\frac{1}{2} + m - i \kappa)}{\Gamma(-i \kappa) \Gamma(\frac{1}{2} - m) \Gamma(\frac{1}{2} + m)},
\]
for real \( m \). For half-integer \( m \) we recover of course (17b).

It should be emphasized that the new viewpoint presented here is the association of the \( \text{sp}(2,R) \) Casimir operator of an algebra with the Schrödinger PT Hamiltonian. We quote here the work of Basu and Wolf,\(^{15}\) which identifies the spectrum of this system with the Clebsch-Gordan series of a certain class of \( \text{sp}(2,R) \) couplings and the wave functions with Clebsch-Gordan coefficients. We have dealt with \( \text{sp}(2,R) \) since an \( N \)-particle \( \text{sp}(2N,R) \) formulation of the most general PT system is yet to be completed.\(^{13}\) This should be relevant for \( N \)-body systems describing scattering processes in atomic and nuclear collisions.

We would like to thank Y. Alhassid, J. Lomnitz, M. Moshinsky, and L. F. Urrutia for very useful discussions. This work was supported in part by Consejo Nacional de Ciencia y Tecnologia de Mexico Project No. PCCBCEU-020061.
